

**AWS Capstone Use Case 12****Containerizing Lambda deployments using OCI container images**

Each use case report should have following sections:

Sections	Points
Implemented Solution <a href="#">Architecture diagram</a> with detailed explanation for each component / service used.	8
<a href="#">Implementation Screenshot</a> with brief description for every screenshot. Code / Script files (if applicable) <i>Screen shots must have your AWS / Azure account ID clearly visible along with your laptop's date and time</i>	8
<a href="#">Cost Analysis</a> of the implemented Solution – Assume your solution is used by 1000 users for a month, and give monthly billing estimates.	2
<a href="#">Lessons &amp; Observations</a>	2
<b>TOTAL (for 1 use case)</b>	<b>20</b>

**A. Implemented Solution Architecture diagram with detailed explanation for each component / service used.**

Implemented Solution Architecture Diagram: Lambda Containerization

## Steps for Lambda Containerization using OCI Images:

- Configure EC2
- Use SSH to securely login to EC2
- Securely copy files required to build docker image on EC2
- Configure ECR with a private repository to store docker image
- Push the Docker image from EC2 to a private repository in ECR
- Create Lambda function in ECR: Build and tag the lambda function
- Invoke the Lambda Function
- Access Lambda function using API Gateway

## Components/Services Used:

- **Amazon EC2:** Compute service from AWS. Used as a local machine to process files required to build container image.
- **Amazon ECR:** used to store the container image in private repository
- **Amazon IAM:** Used for permissions
- **Amazon Lambda:** Serverless compute service from AWS. Used to deploy container image. There are 3 ways to create lambda function;1) author from scratch 2) use a blueprint and 3) use container image.
- **API Gateway:** To make deployed image accessible
- **Python and Text files required to build container image:**
  - **Requirements.txt file** contains all packages that are required in app.py file
  - **app.py file** imports all packages required to build lambda function. It defines a function `lambda_handler`. The handler function accepts two arguments; event and context. The event argument retrieves the data that is passed to execute the lambda function. For e.g. if the lambda function is triggered using HTTP API call via API Gateway then the event calls for all parameters required for HTTP API call (resource, path, method, resource path, headers etc). The context argument provides the data about the execution environment of the lambda function. The `lambda_handler` function must have a return value that depends on the invocation type. For example `statusCode 200` is returned when lambda function is invoked using HTTP API call indicating that the request for invoking lambda is successful. `Statuscode 200` is success response code. The meaning of a success depends on the HTTP request method: `GET` : The resource has been fetched and is transmitted in the message body (`Hello from Lambda Containers`).
  - **Dockerfile** contains **python 3.8** lambda base image which is picked up from `public.ecr.aws`. The Dockerfile installs all packages and dependencies included in `requirements.txt` file. It copies the `app.py` to the container and sets the command for `app.handler`.

## Commands for Lambda Containerization:

```
user@user-HP-Pavilion-14-Notebook-PC:~/Downloads$ chmod 400 sk33.pem; providing
read access to the owner of sk33.pem
user@user-HP-Pavilion-14-Notebook-PC:~/Downloads$ ssh -i "sk33.pem" ec2-
user@ec2-3-82-206-232.compute-1.amazonaws.com; secure login to EC2
```

### **Building Docker Image on EC2:**

```
[ec2-user@ip-172-31-88-107 ~]$ mkdir lambda-docker
[ec2-user@ip-172-31-88-107 ~]$ cd lambda-docker/
[ec2-user@ip-172-31-88-107 lambda-docker]$ ls

[ec2-user@ip-172-31-88-107 lambda-docker]$ vim app.py
[ec2-user@ip-172-31-88-107 lambda-docker]$ ls
app.py
[ec2-user@ip-172-31-88-107 lambda-docker]$ vim Dockerfile
[ec2-user@ip-172-31-88-107 lambda-docker]$ ls
app.py Dockerfile
[ec2-user@ip-172-31-88-107 lambda-docker]$ vim requirements.txt
[ec2-user@ip-172-31-88-107 lambda-docker]$ ls
app.py Dockerfile requirements.txt

[ec2-user@ip-172-31-88-107 home]$ sudo apt-get update

[ec2-user@ip-172-31-88-107 home]$ sudo amazon-linux-extras install docker

[ec2-user@ip-172-31-88-107 home]$ sudo service docker start

[ec2-user@ip-172-31-88-107 home]$ sudo chkconfig docker on

[ec2-user@ip-172-31-88-107 home]$ sudo yum install -y git

[ec2-user@ip-172-31-88-107 home]$ sudo curl -i -L
https://github.com/docker/compose/releases/download/docker-compose-
$(uname -s)-$(uname -m) -o /usr/local/bin/docker-compose

[ec2-user@ip-172-31-88-107 ~]$ sudo chmod +x /usr/local/bin/docker-compose
[ec2-user@ip-172-31-88-107 ~]$ docker-compose version
Docker Compose version v2.11.0
[ec2-user@ip-172-31-88-107 ~]$ docker images
```

### **Commands to push build Docker image to ECR:**

```
aws ecr get-login-password --region us-east-1 | docker login --username AWS --
password-stdin 204298662877.dkr.ecr.us-east-1.amazonaws.com
```

### **Commands to run above aws ecr get-login-password command successfully:**

```
[ec2-user@ip-172-31-88-107 ~]$ sudo apt-get install gnupg2 pass
[ec2-user@ip-172-31-88-107 lambda-docker]$ sudo amazon-linux-extras install epel -y
[ec2-user@ip-172-31-88-107 ~]$ sudo apt install awscli -y

[ec2-user@ip-172-31-88-107 ~]$ pwd
/home/ec2-user
[ec2-user@ip-172-31-88-107 ~]$ cd .aws
[ec2-user@ip-172-31-88-107 .aws]$ ls
config credentials
```

```
[ec2-user@ip-172-31-88-107 .aws]$ cd credentials
-bash: cd: credentials: No such file or directory
[ec2-user@ip-172-31-88-107 .aws]$ cat credentials
[default]
aws_access_key_id =
[[ec2-user@ip-172-31-88-107 .aws]$ vi credentials
[ec2-user@ip-172-31-88-107 .aws]$ cat credentials
[default]
aws_access_key_id = AKIAS7EJGGPOY4PQ63GB
aws_secret_access_key = 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
[ec2-user@ip-172-31-88-107 .aws]$ cd ..
[ec2-user@ip-172-31-88-107 ~]$ pwd
/home/ec2-user
```

### **Commands to build and tag the docker image:**

docker build -t docker-lambda .

```
docker tag docker-lambda:latest 204298662877.dkr.ecr.us-east-
1.amazonaws.com/docker-lambda:latest
```

### **Command to push the built docker image to private repository in ECR:**

docker push 204298662877.dkr.ecr.us-east-1.amazonaws.com/docker-lambda:latest

### **Successful implementation of Docker image Push commands:**

```
[ec2-user@ip-172-31-88-107 lambda-docker]$

[ec2-user@ip-172-31-88-107 ~]$ pwd
/home/ec2-user

[ec2-user@ip-172-31-88-107 lambda-docker]$ ls
app.py Dockerfile
[ec2-user@ip-172-31-88-107 lambda-docker]$ vim requirements.txt
[ec2-user@ip-172-31-88-107 lambda-docker]$ ls
app.py Dockerfile requirements.txt
[ec2-user@ip-172-31-88-107 lambda-docker]$ 

```

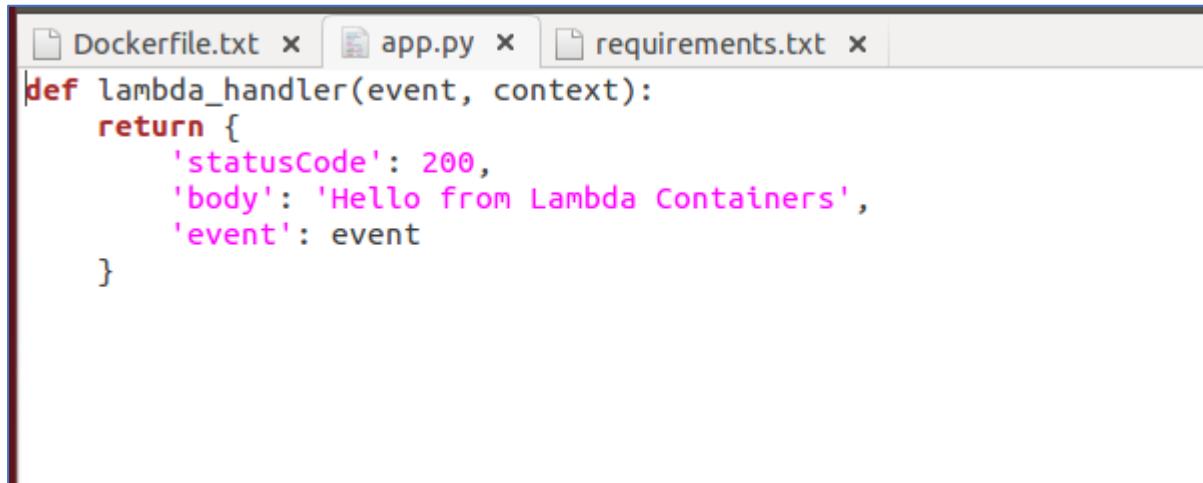

- Created lambda-docker directory in EC2 and copied all required files (app.py, Dockerfile and requirements.txt) in the directory

The screenshot shows a GIMP interface titled "requirements.txt (~/Downloads) - gedit". The window contains three tabs: "Dockerfile.txt", "app.py", and "requirements.txt". The "requirements.txt" tab is active, displaying the following text:

```
boto3>=1.16.19
requests>=2.25.0
```

5. Requirements.txt file contains all packages that are required in app.py file

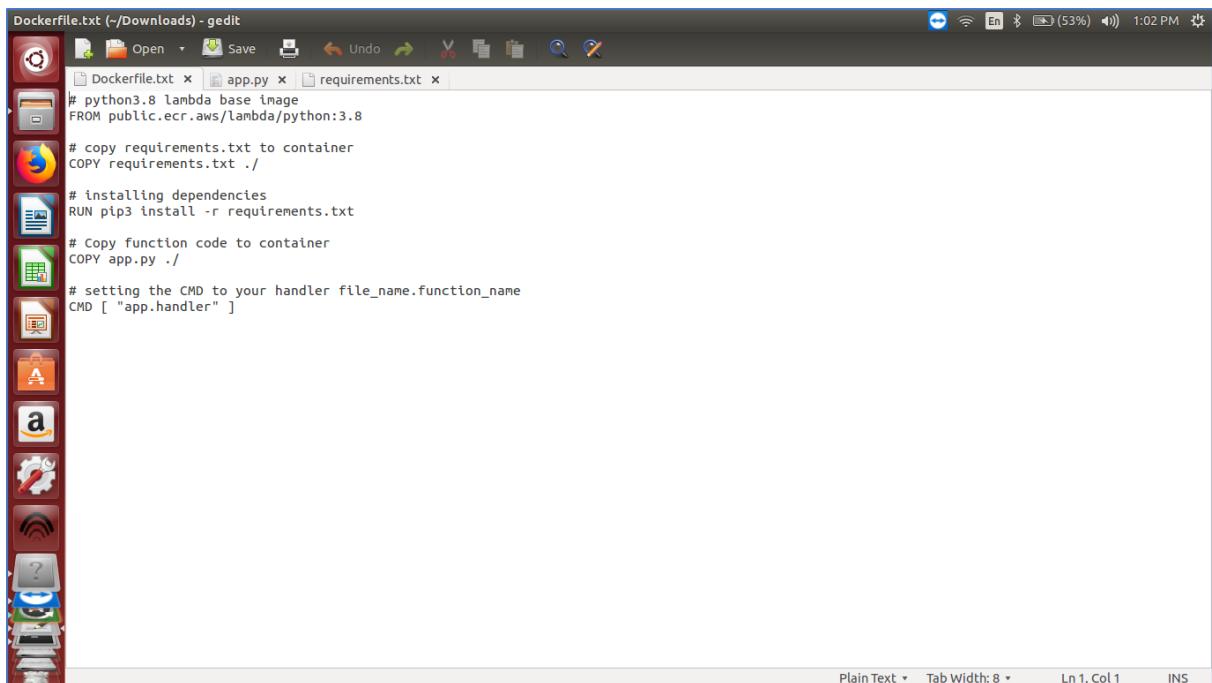

The screenshot shows a code editor window with three tabs: "Dockerfile.txt", "app.py", and "requirements.txt". The "app.py" tab is active, displaying the following Python code:

```
def lambda_handler(event, context):
    return {
        'statusCode': 200,
        'body': 'Hello from Lambda Containers',
        'event': event
    }
```

6. App.py file

app.py file imports all packages required to build lambda function. It defines a function `lambda_handler`. The handler function accepts two arguments; event and context. The event argument retrieves the data that is passed to execute the lambda function. For e.g. if the lambda function is triggered using HTTP API call via API Gateway then the event calls for all parameters required for HTTP API call (resource, path, method, resource path, headers etc). The context argument provides the data about the execution environment of the lambda function. The `lambda_handler` function must have a return value that depends on the invocation type. For example `statusCode 200` is returned when lambda function is invoked using HTTP API call indicating that the request for invoking lambda is successful. `StatusCode 200` is success response code. The meaning of a success depends on the HTTP request method: GET : The resource has been fetched and is transmitted in the message body (`Hello from Lambda Containers`).

```

Dockerfile.txt (~/.Downloads) - gedit
# python3.8 lambda base image
FROM public.ecr.aws/lambda/python:3.8

# copy requirements.txt to container
COPY requirements.txt .

# installing dependencies
RUN pip3 install -r requirements.txt

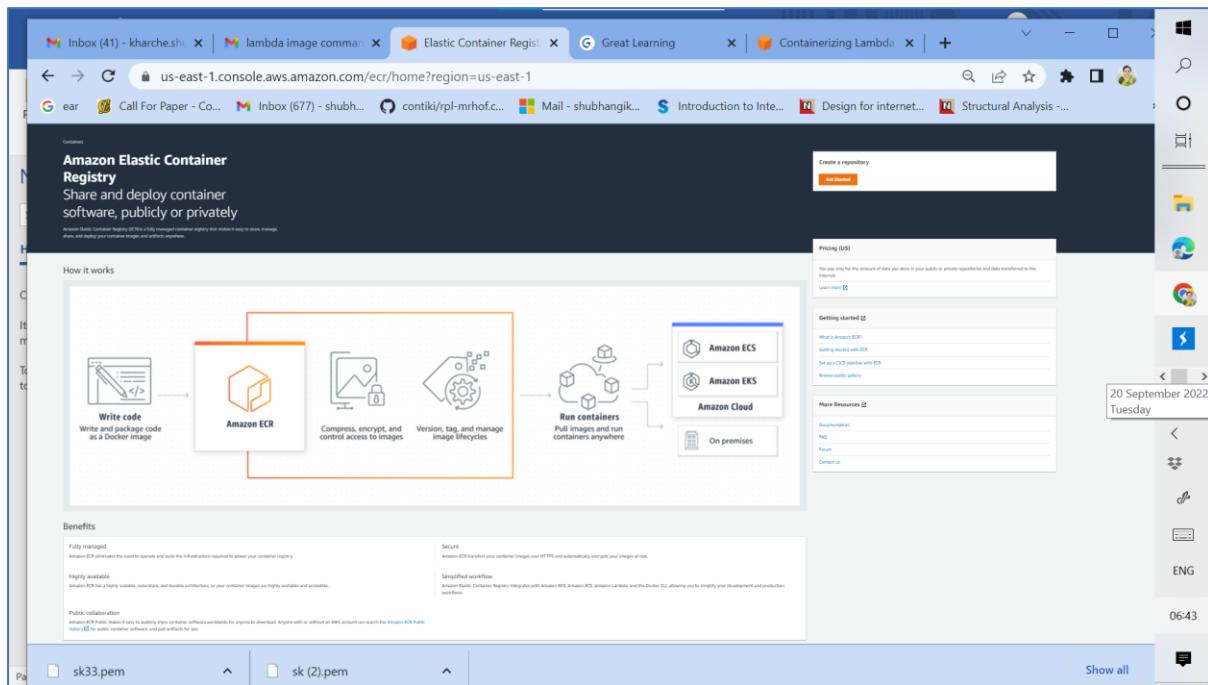

# Copy function code to container
COPY app.py .

# setting the CMD to your handler file_name.function_name
CMD [ "app.handler" ]

```

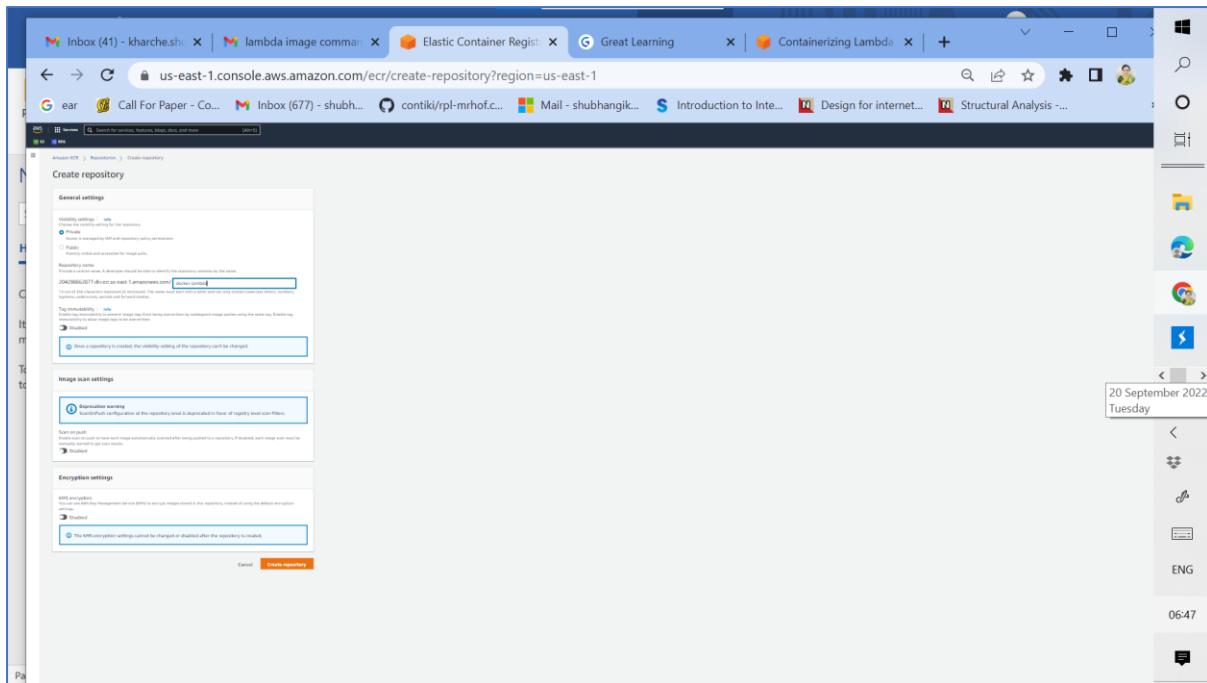

## 7. Dockerfile

Dockerfile contains python 3.8 lambda base image which is picked up from public.ecr.aws. The Dockerfile installs all packages and dependencies included in requirements.txt file. It copies the app.py to the container and sets the command for app.handler.

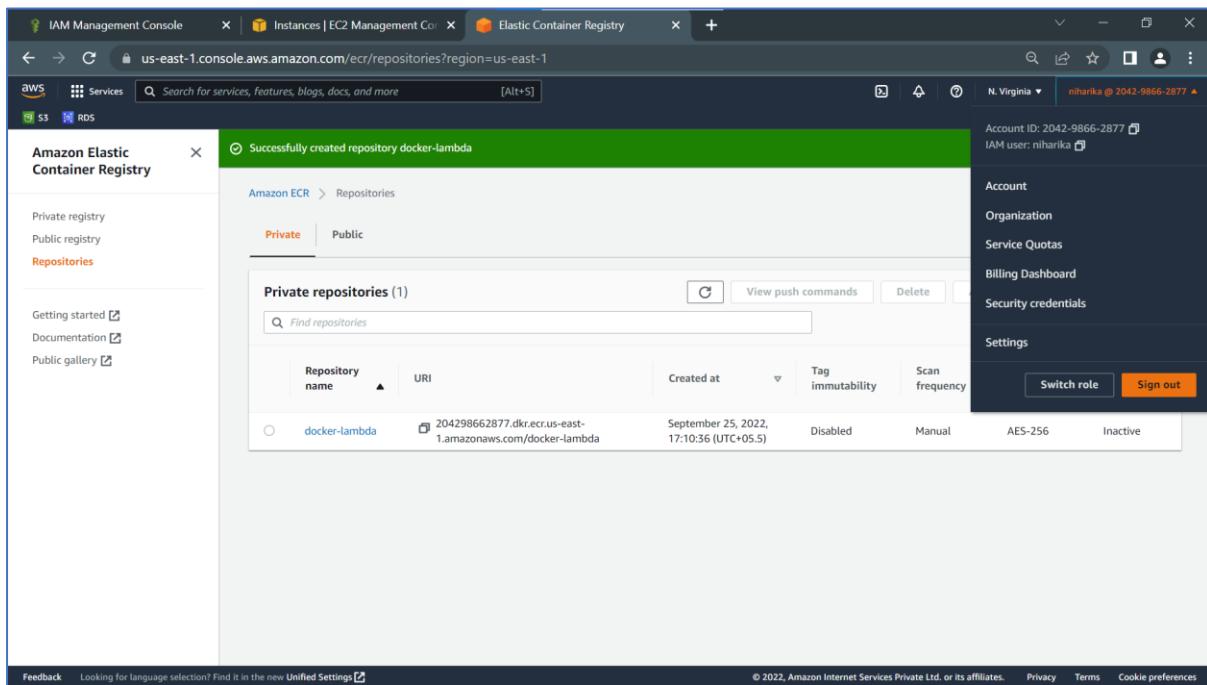

The screenshot shows the Amazon ECR console interface. It includes sections for 'How it works' (describing the process from writing code to running containers), 'Benefits' (listing features like fully managed, highly available, and public utilization), and 'Getting Started' (with links to AWS ECR, ECS, EKS, and Cloud services). A sidebar on the right shows the date as 20 September 2022, Tuesday, and the time as 06:43.

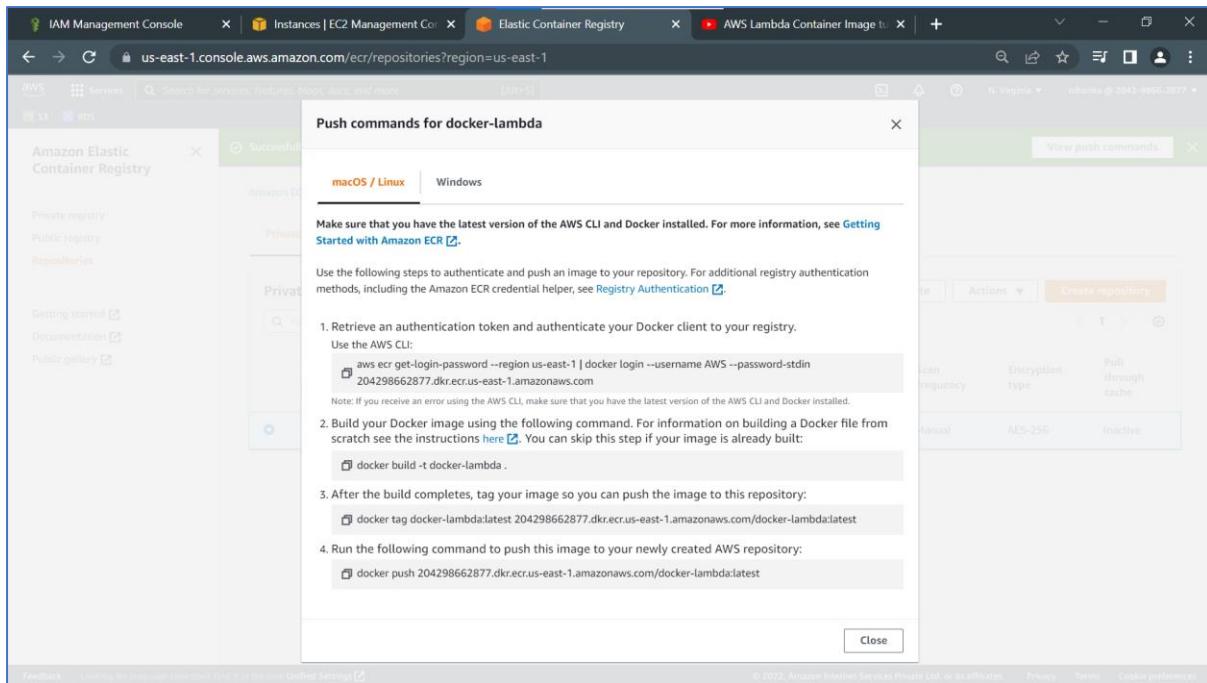

## 8. Browse Amazon ECR in AWS console

#### 9. Create private repository named docker-lambda in Amazon ECR

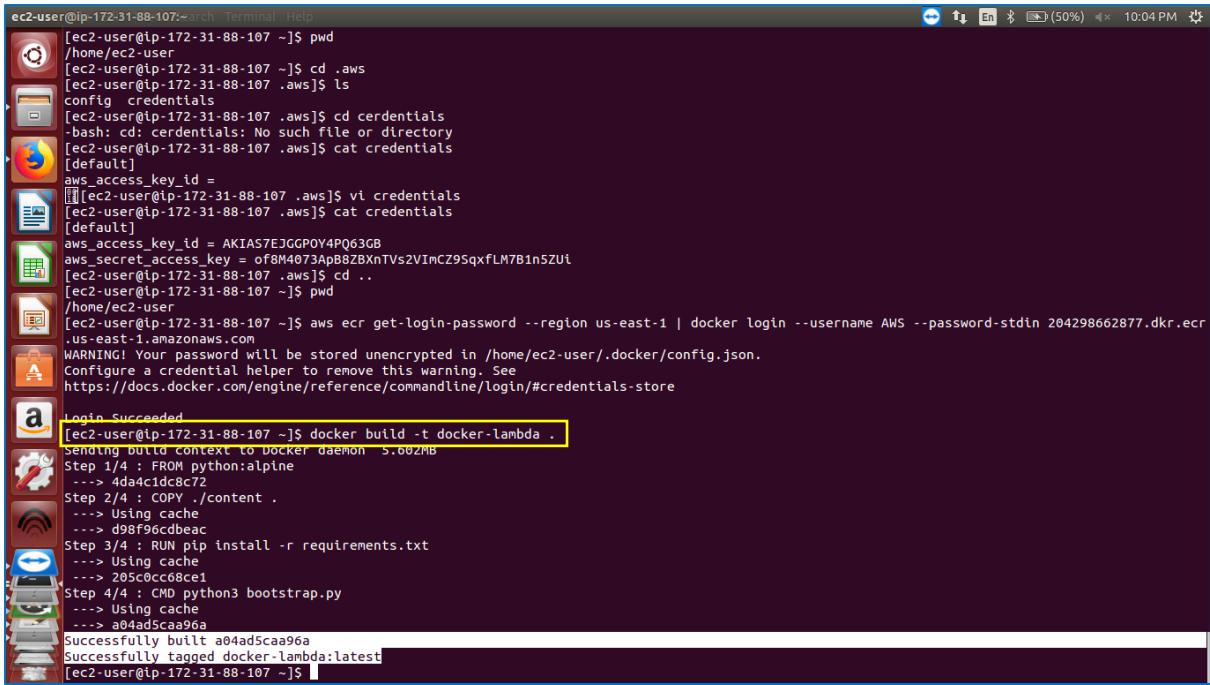

#### 10. Successful creation of private repository named docker-lambda

## 11. Push Commands for docker-lambda repository

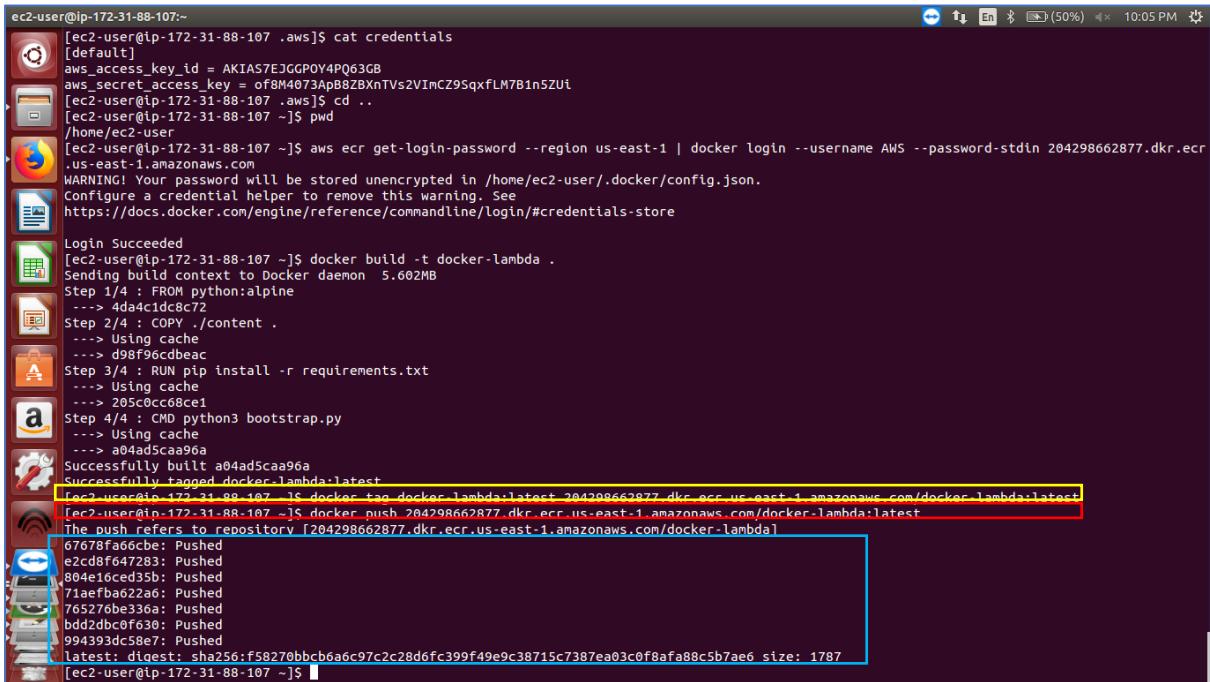

```

### 14. Successfully tagged and pushed docker image to docker-lambda repository

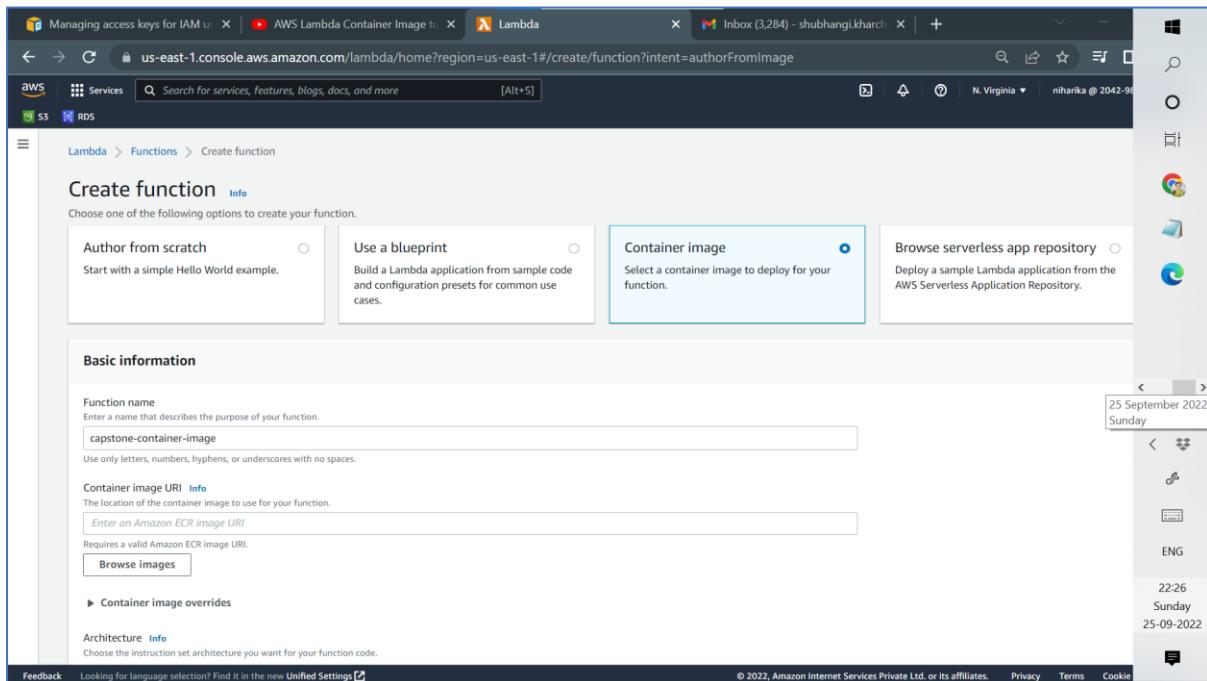

The screenshot shows the AWS Elastic Container Registry (Amazon ECR) interface. The left sidebar shows options like Private registry, Public registry, Repositories, Summary, Images (selected), Permissions, Lifecycle Policy, and Repository tags. The main area shows the 'docker-lambda' repository under 'Amazon ECR > Repositories'. A red box highlights the repository name 'docker-lambda' in the top navigation bar. Another red box highlights the 'Images (1)' table, which lists one image entry: 'latest' (Image type, pushed at September 25, 2022, 22:05:23 UTC+05:5, size 42.82 MB, digest sha256:f58270bbcb6a6c9...).

15. Verified that the docker image tagged latest is available in docker-lambda repository

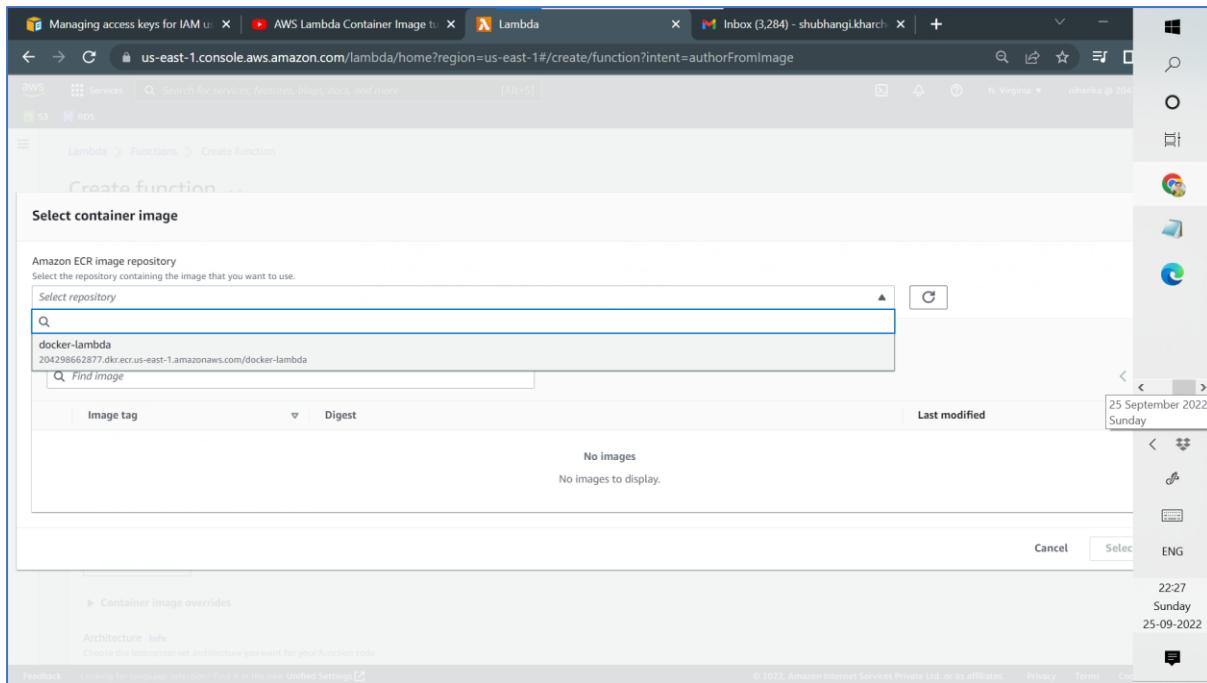

The screenshot shows the AWS Lambda console. The left sidebar shows options like Dashboard, Applications, Functions (selected), Additional resources, and Related AWS resources. The main area shows the 'Functions (0)' page with a search bar and a table header: Function name, Description, Package type, Runtime, and Last modified. A red box highlights the 'Create function' button in the top right corner of the main content area.

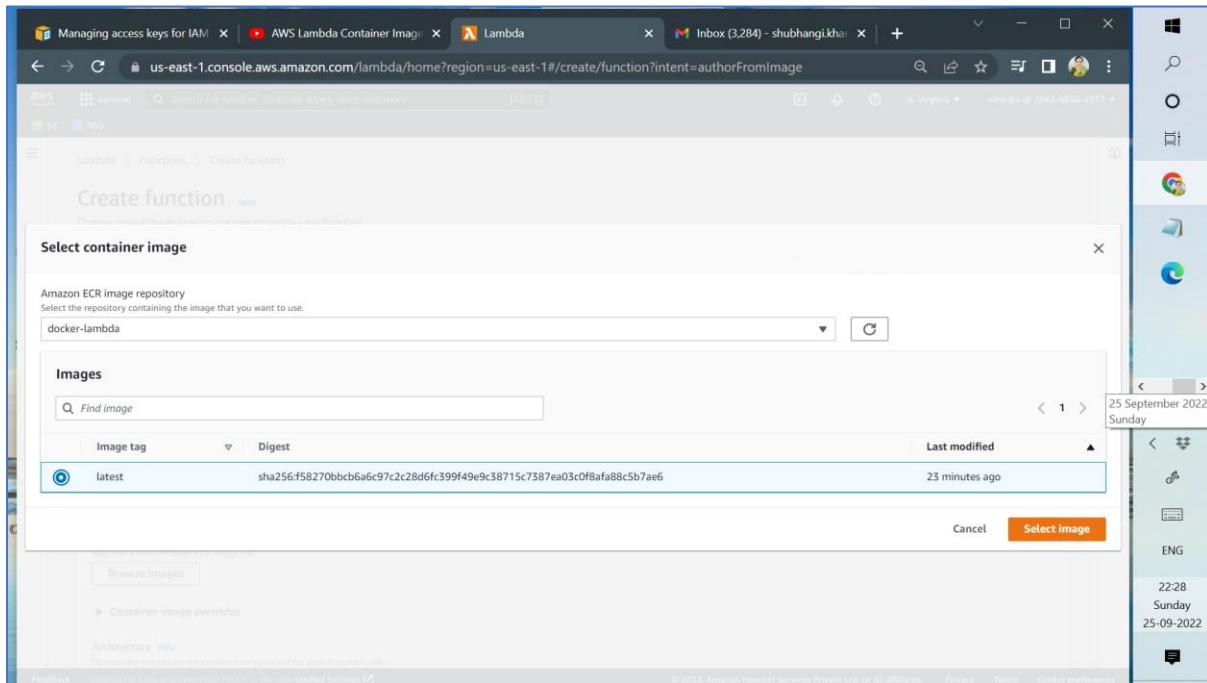

## 16. Browse lambda from AWS console and create lambda function

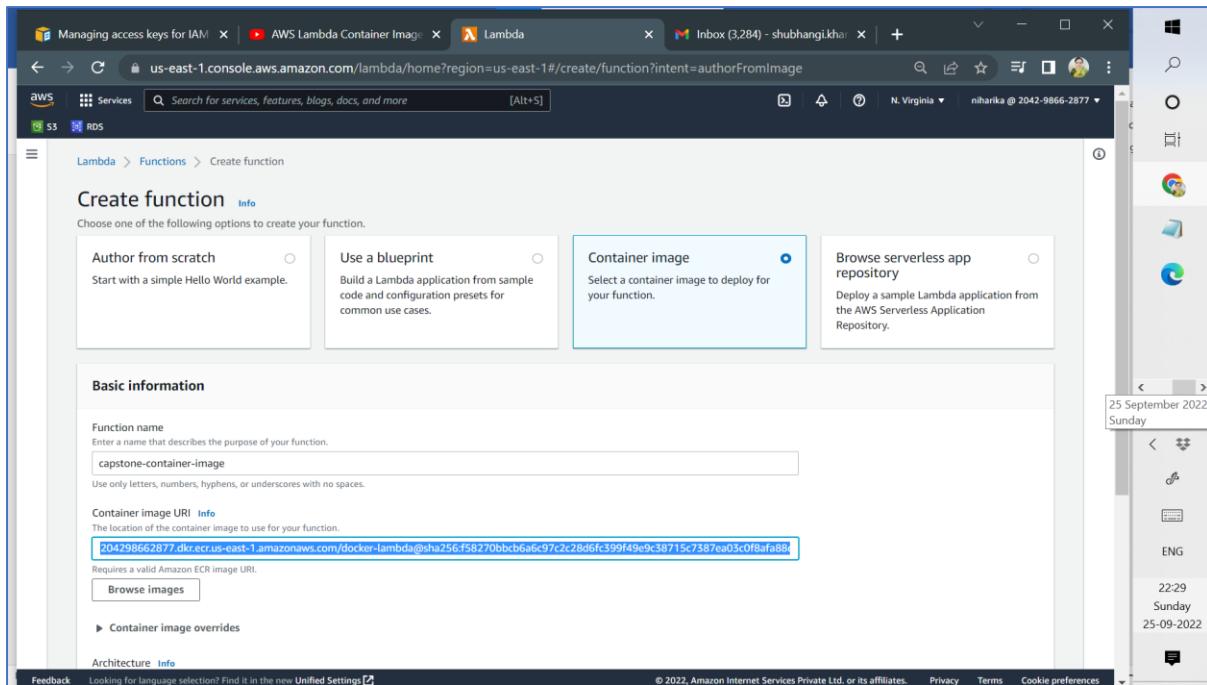

## 17. Create lambda function using container image

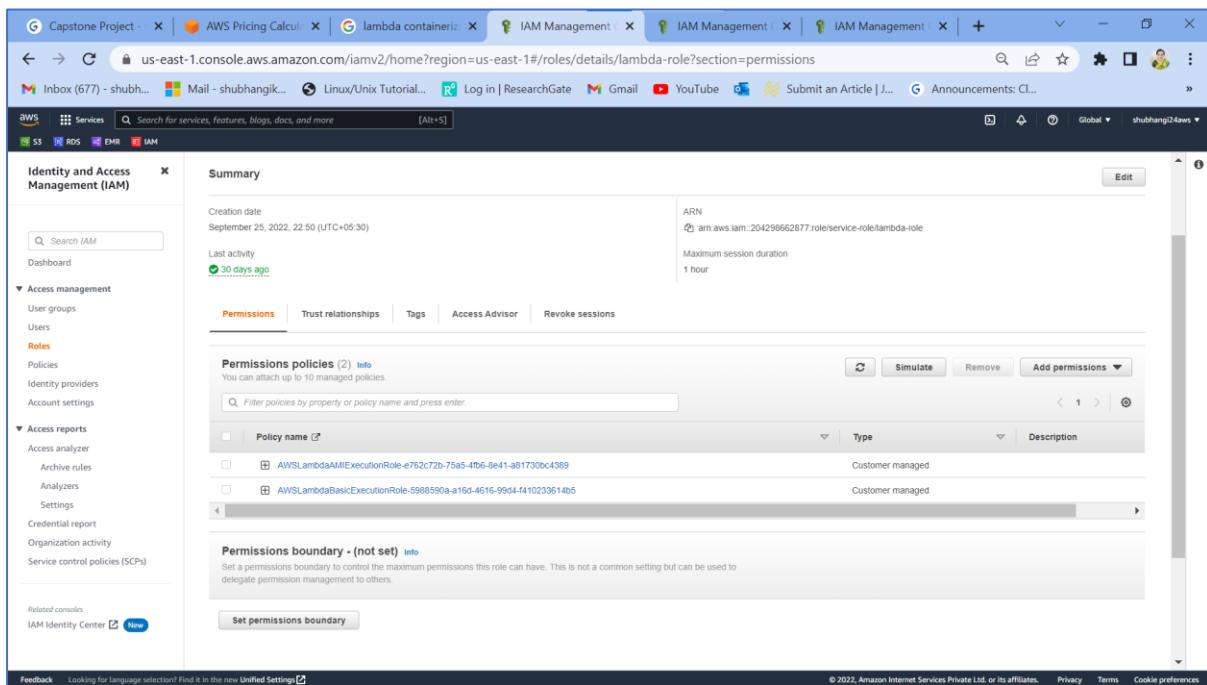

## 18. Browse the container image from docker-lambda repository

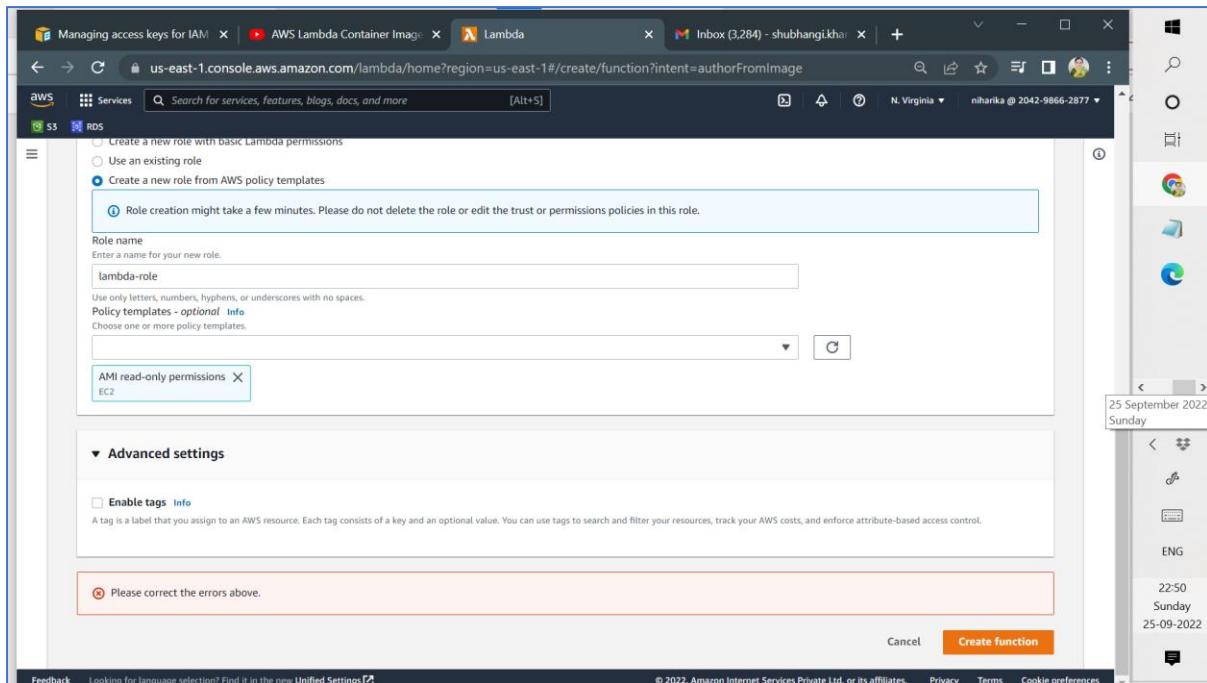

## 19. Select the container image from docker-lambda repository

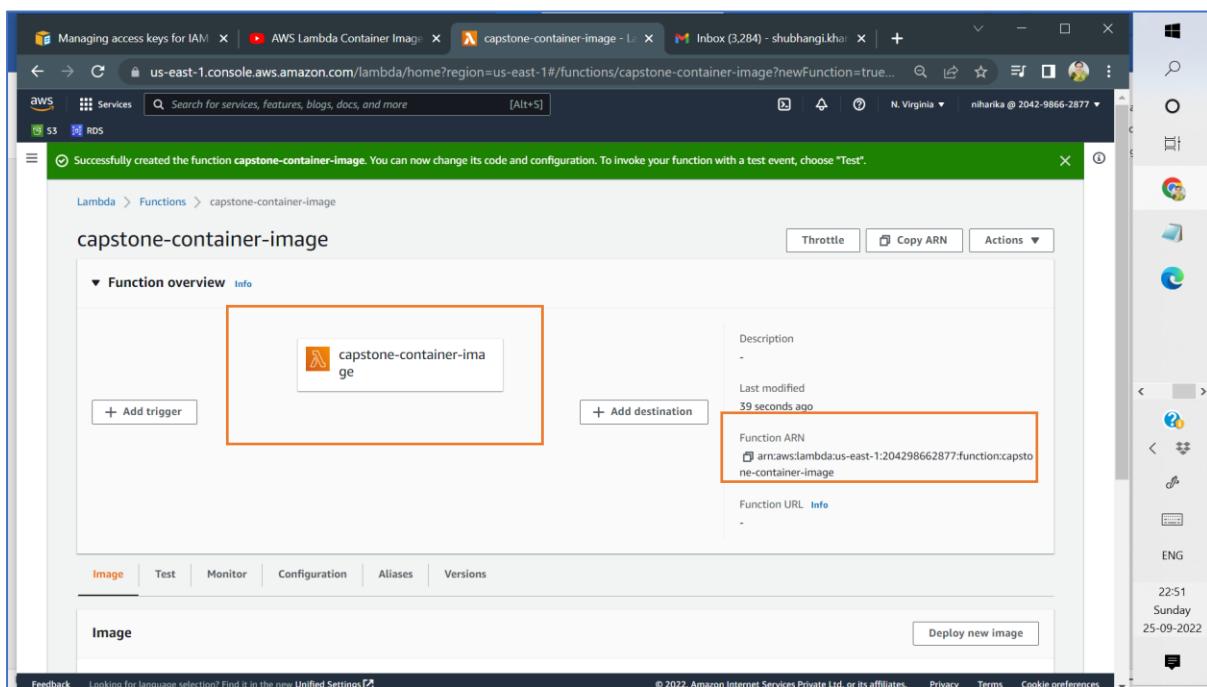

## 20. Provide container image URI

## 21. Separately create IAM role to provide read permissions from EC2 to lambda function

## 22. Enter created role name and hit create function

## 23. Successfully created lambda function named capstone-container-image

The screenshot shows the AWS Lambda console interface. A green banner at the top indicates that the function has been successfully created. The main area displays the 'capstone-container-image' function details. The 'Image' tab is active, showing the deployed container image information. The 'Architecture' field is highlighted with a red box and contains the value 'x86\_64'.

24. Lamba function capstone-container-image is created using x86\_64 architecture

The screenshot shows the 'Test event' configuration page for the 'capstone-container-image' function. The 'Event JSON' field is highlighted with a red box and contains the following JSON input:

```
[{"key1": "value1", "key2": "value2", "key3": "value3"}]
```

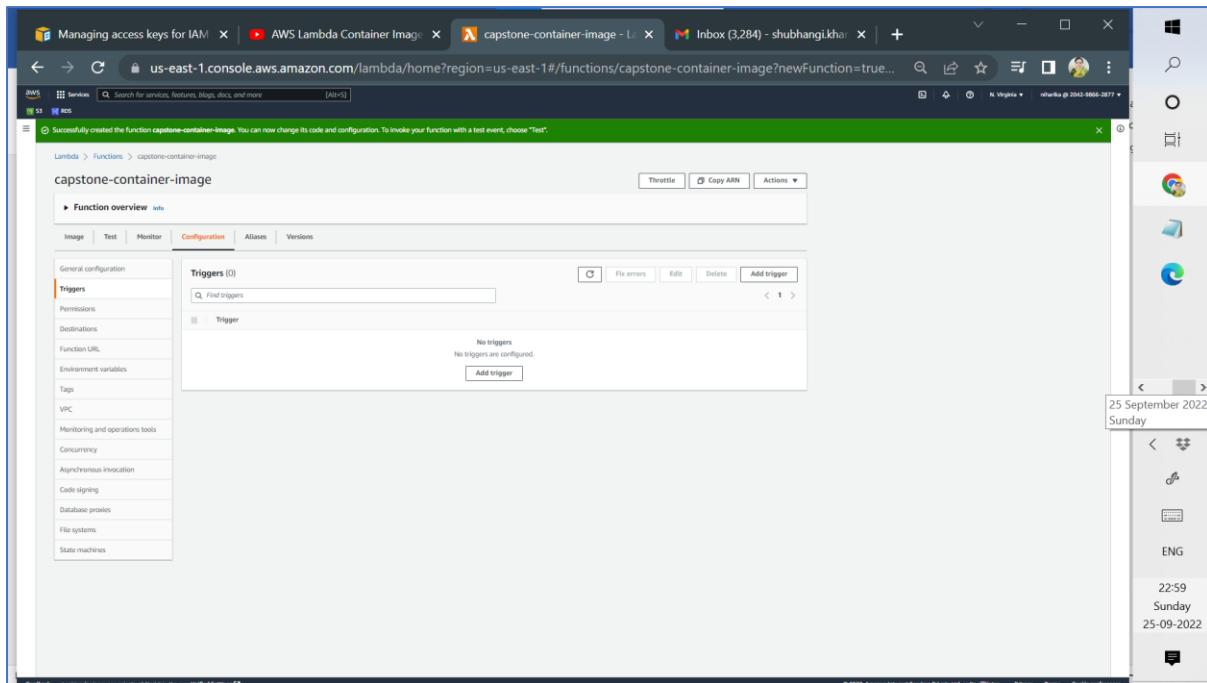

25. Invoking lambda function using JSON event. Test event provides JSON input to the lambda function

The screenshot shows the AWS Lambda console for the function 'capstone-container-image'. A success message at the top states 'Successfully created the function capstone-container-image. You can now change its code and configuration. To invoke your function with a test event, choose "Test".' Below this, the 'Execution result: succeeded' section shows a JSON response body containing the message 'Hello from lambda containers'. The 'Log output' section displays CloudWatch logs for the execution, including the start and end requests and a report request. The 'Test event' section allows for creating a new test event or editing an existing one.

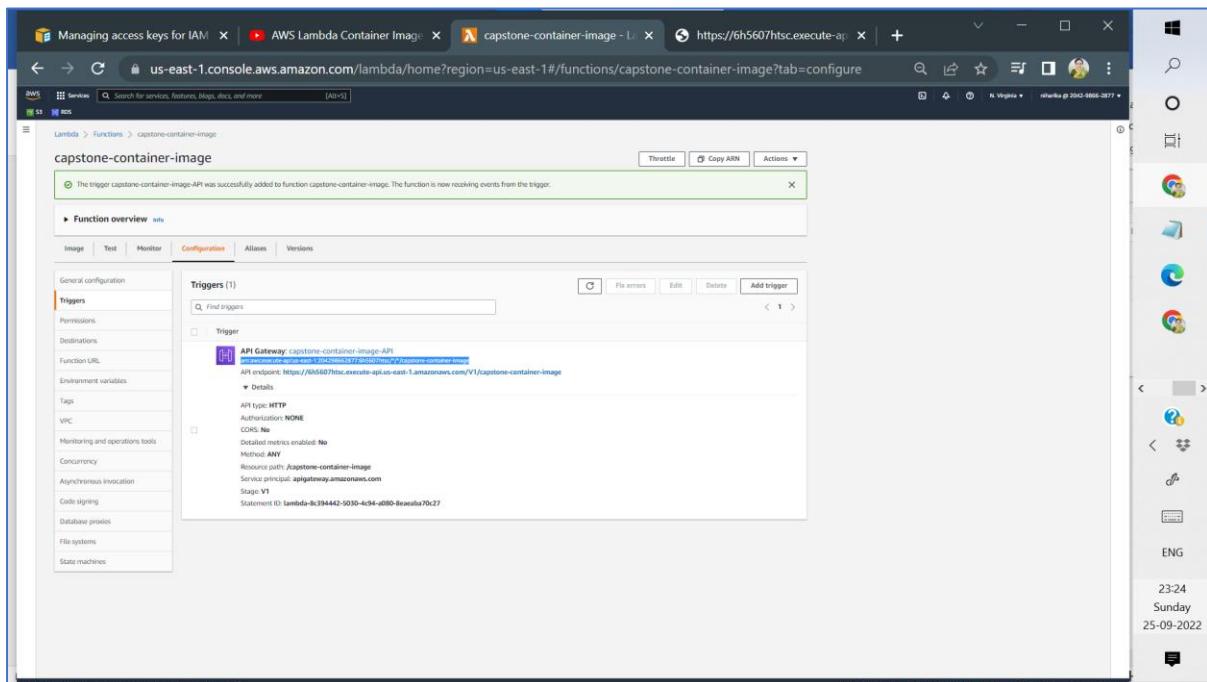

26. Test event execution is successful. Status code 200 indicates that the response has been fetched successfully and added to the message body, Lambda function is invoked successfully. Note the message body includes the message “Hello from lambda containers” which is part of lambda\_handler function event attribute in app.py file.

The screenshot shows the AWS Lambda function configuration page for 'capstone-container-image'. In the 'General configuration' section, the 'Memory' setting is listed as 128 MB and the 'Ephemeral storage' setting is listed as 512 MB. Both settings are highlighted with red boxes. The left sidebar lists various configuration options like Triggers, Permissions, Destinations, and AWS Compute Optimizer.

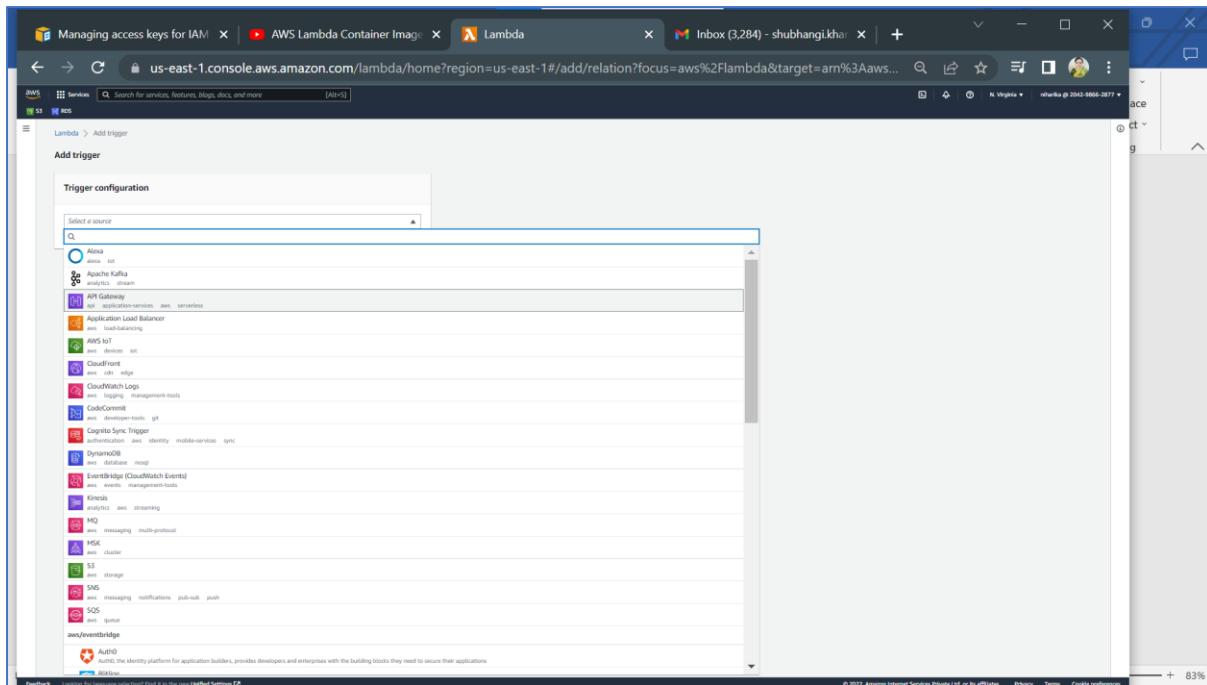

27. Lambda function capstone-container-image is configured to 128MB memory and 512 MB ephemeral storage

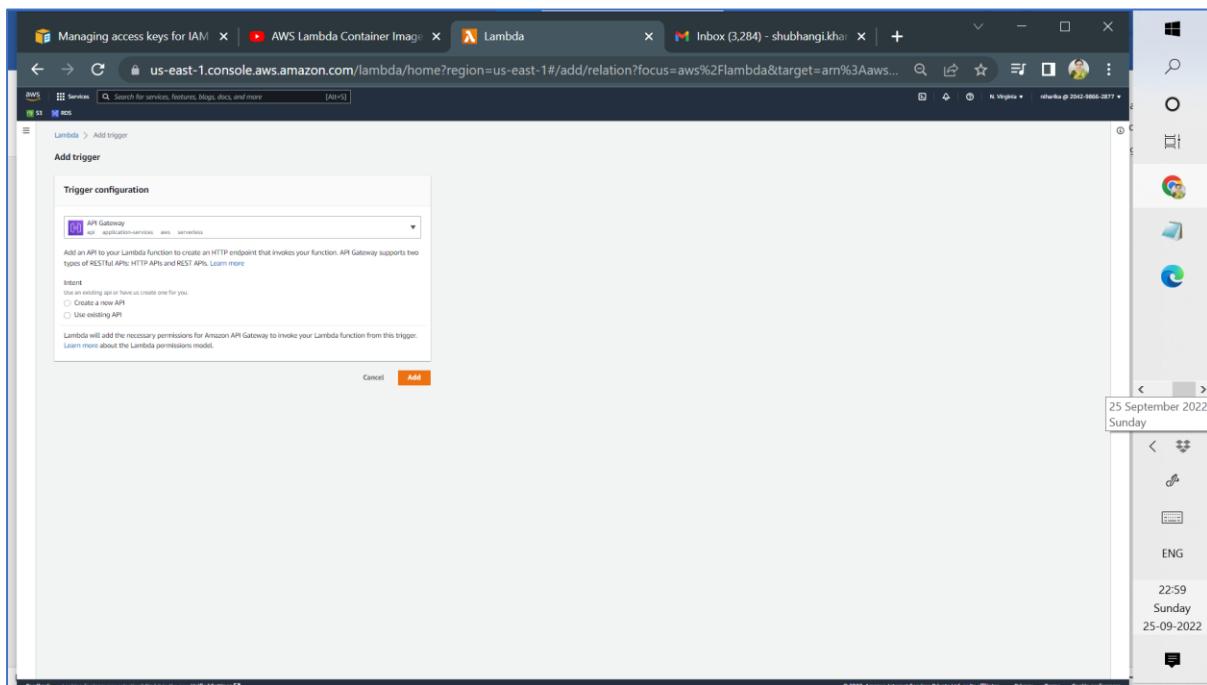

## 28. Adding trigger to lambda function

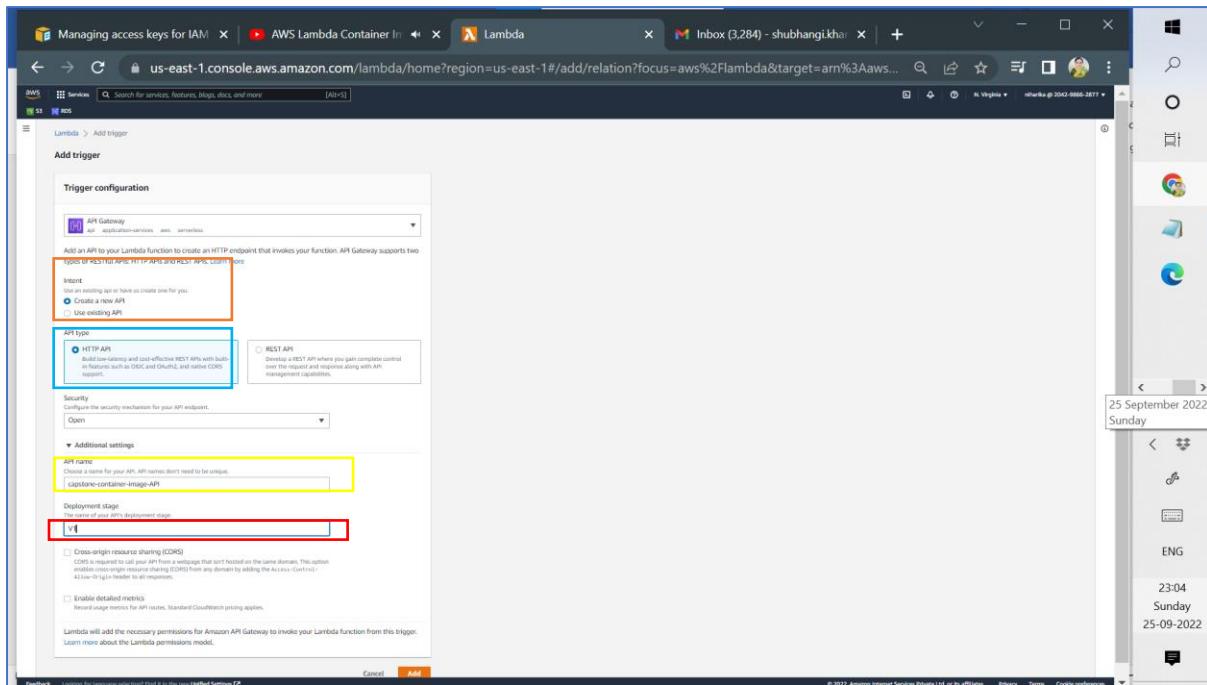

## 29. Adding trigger to lambda function using API Gateway

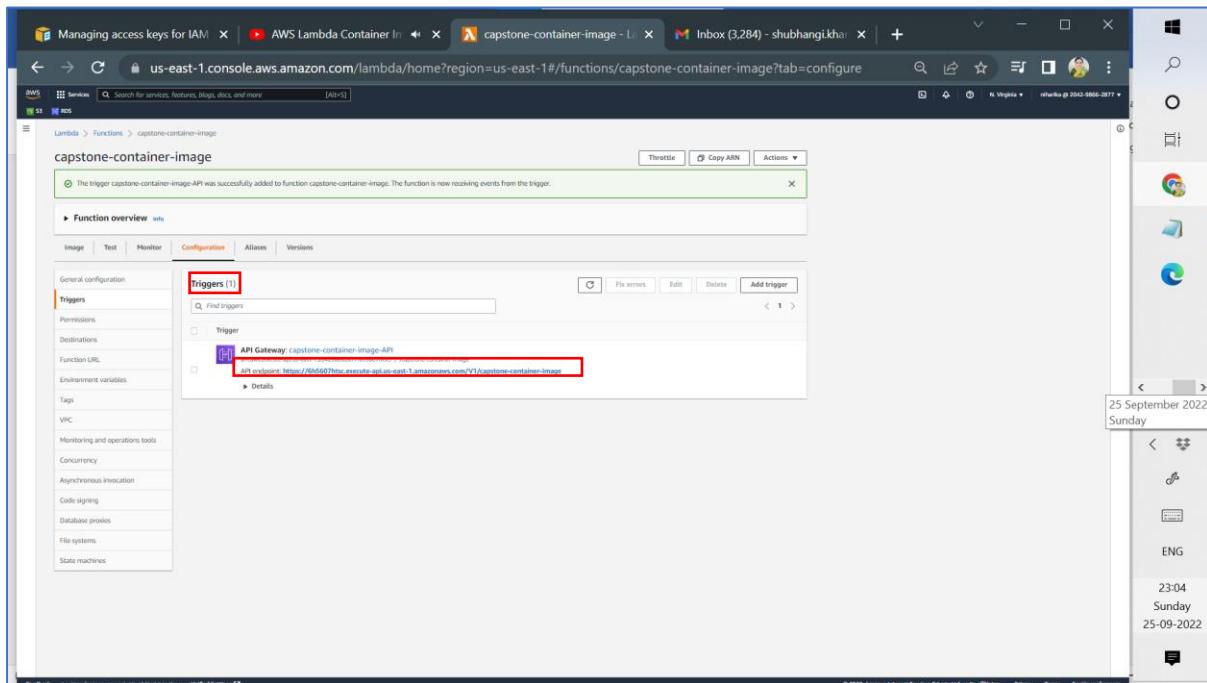

### 30. Selecting trigger configuration as API Gateway

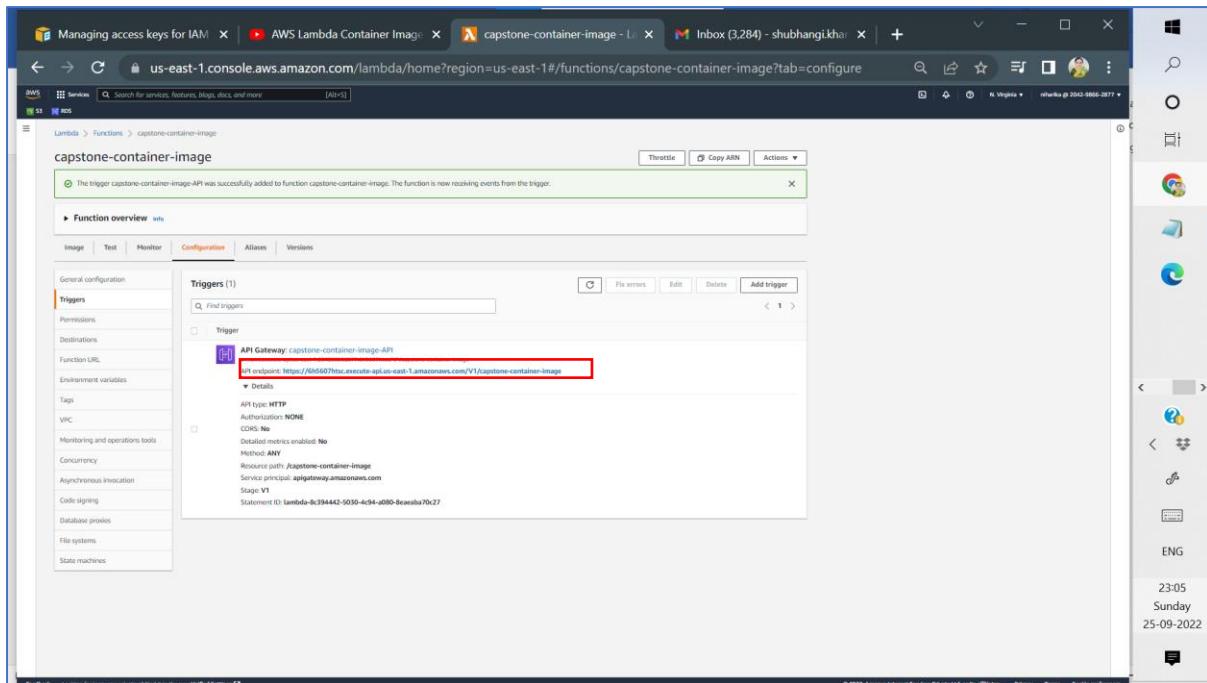

### 31. Selected API Gateway as trigger configuration

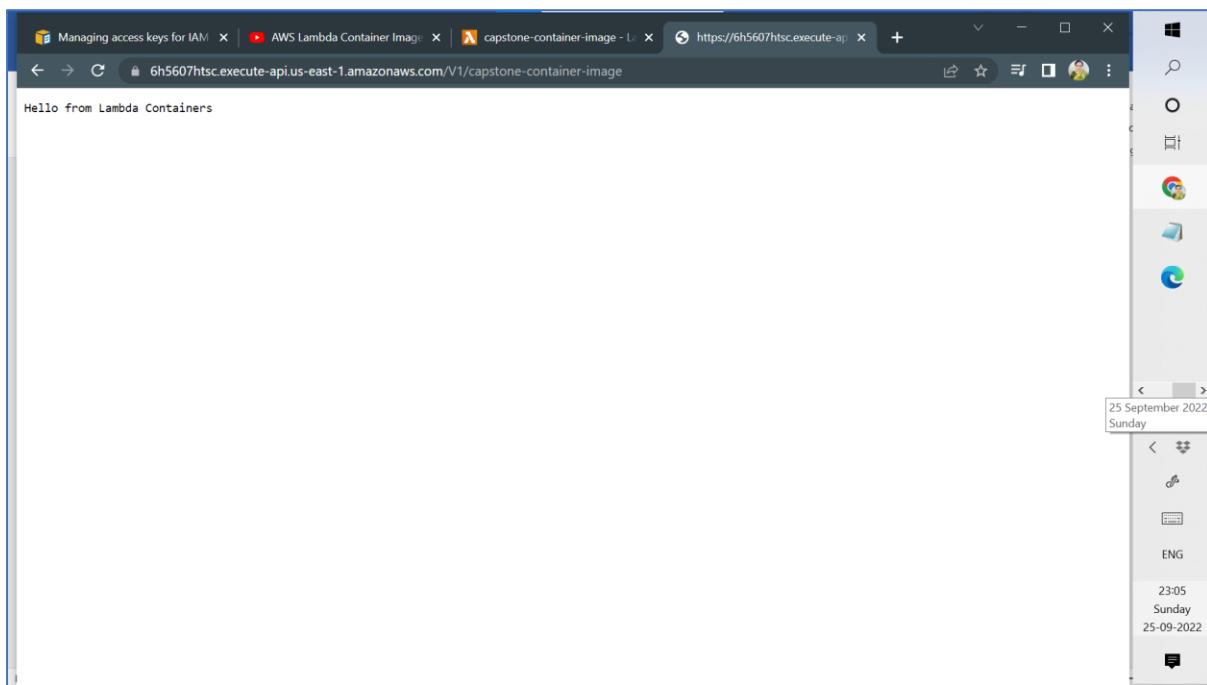

### 32. Creating new API with HTTP API Type and deployment stage name as V1

### 33. Trigger API Gateway is successfully added to lambda function capstone container image. The function will now receive events from the trigger. Note API endpoint URL for accessing lambda function

34. Details of API Gateway trigger. Type: HTTP, authorization: None, CORS: No, detailed metrics enabled: No, HTTP method: ANY, deployment stage V1

35. Lambda function capstone-container-image accessed successfully using API endpoint URL. "Hello from lambda containers" message received in lambda function is same as the one sent using JSON event.

**C. Cost Analysis of the implemented Solution –Assume your solution is used by 1000 users for a month, and give monthly billing estimates.**

Sr. No	Region	Services	Upfront	monthly	For 1000 users	First 12 months	currency	Configuration summary	Calculations
1	US East (N virginia)	Amazon EC2	0.00	8.26	8260	99120	USD	Operating system (Linux), Quantity (1), Pricing strategy (EC2 Instance Savings Plans 1 Year No Upfront), Storage amount (30 GB), Instance type (t2.micro)	EC2 Instance Savings Plans rate for t2.micro in the US East (N. Virginia) for 1 Year term and No Upfront is 0.0072 USD Hours in the commitment: 365 days * 24 hours * 1 year = 8760.0000 hours Total Commitment: 0.0072 USD * 8760 hours = 63.0720 USD Upfront: No Upfront (0% of 63.072) = 0.0000 USD Hourly cost for EC2 Instance Savings Plans = (Total Commitment - Upfront cost)/Hours in the term: (63.072 - 0)/8760 = 0.0072 USD *Please note that you will pay an hourly commitment for Savings Plans and your usage will be accrued at a discounted rate against this commitment. Pricing calculations 1 instances x 0.0072 USD x 730 hours in month = 5.26 USD (monthly instance savings cost) Amazon EC2 Instance Savings Plans instances (monthly): 5.26 USD
2	US East (N virginia)	Amazon ECR	0.00	0.19	190	2280	USD	Amount of data stored (1 GB per month)	1 GB per month x 0.10 USD = 0.10 USD Elastic Container Registry pricing (monthly): 0.10 USD Inbound: Internet: 1 GB x 0 USD per GB = 0.00 USD Outbound: Internet: 1 GB x 0.09 USD per GB = 0.09 USD Data Transfer cost (monthly): 0.09 USD Elastic Container Registry pricing (Monthly): 0.10 USD Data Transfer cost (Monthly): 0.09 USD
3	US East (N virginia)	AWS Lambda	0.00	0.00	0.00	0.00	USD	Lambda function with 1000 requests per month	Data transfer cost between SNS and lambda in same region is 0.00 USD
4	US East (N virginia)	API Gateway	0.00	0.00	0.00	0.00	USD	1000 requests per month	34 KB per request / 512 KB request increment = 0.06640625 request(s) RoundUp (0.06640625) = 1 billable request(s) 1 requests per month x 1,000 unit multiplier x 1 billable request(s) = 1,000 total billable request(s) Tiered price for: 1000 requests 1000 requests x 0.0000010000 USD = 0.00 USD Total tier cost = 0.0010 USD (HTTP API requests) HTTP API request cost (monthly): 0.00 USD.
5	US East (N virginia)	IAM role	0.00	0.00	0.00	0.00	USD	IAM is offered at no additional charge.	IAM role for EC2 to provide full access to aws lambda
		Total	0.00	8.45	8450	101400			

## D. Lessons & Observations

- Learnt that there are 3 ways to create lambda function; 1) author from scratch 2) use a blueprint and 3) use container image.
- Learnt to create lambda function from container image in details
- **Learnt to use API Gateway for accessing deployed image**
- **Learnt to build container image using following 3 files:**
  - a. **Requirements.txt file** contains all packages that are required in app.py file
  - b. **app.py file** imports all packages required to build lambda function. It defines a function lambda\_handler. The handler function accepts two arguments; event and context. The event argument retrieves the data that is passed to execute the lambda function. For e.g. if the lambda function is triggered using HTTP API call via API Gateway then the event calls for all parameters required for HTTP API call (resource, path, method, resource path, headers etc). The context argument provides the data about the execution environment of the lambda function. The lambda\_handler function must have a return value that depends on the invocation type. For example statusCode 200 is returned when lambda function is invoked using HTTP API call indicating that the request for invoking lambda is successful. StatusCode 200 is success response code. The meaning of a success depends on the HTTP request method: GET : The resource has been fetched and is transmitted in the message body (Hello from Lambda Containers).
  - c. **Dockerfile** contains python 3.8 lambda base image which is picked up from public.ecr.aws. The Dockerfile installs all packages and dependencies included in requirements.txt file. It copies the app.py to the container and sets the command for app.handler.
- Learnt Docker push commands to push built docker container image from EC2 to ECR
- Learnt to create private ECR
- Learnt to troubleshoot errors while using push commands
- Learnt to create IAM role for EC2 to provide full access to AWS Lambda
- Learnt to estimate cost for each service
- Lambda is a serverless compute service from AWS
